SD FC Pricing Intelligence — View Guide

Detailed Explanation of Each Dashboard View

Pricing Workshop — What-If Simulator

The Pricing Workshop lets you experiment with price changes and see the impact in real time before committing to any decision. It is the most hands-on view in the platform.

How to use it

1. Select a game and section from the dropdowns at the top. The view shows three KPI cards: the current face price, the secondary market average (what fans actually pay on StubHub/SeatGeek), and the section capacity.

2. Drag the price slider up or down. The range goes from 70% to 150% of face price. Four metrics update instantly as you move the slider:

- Projected Attendance — how many seats you expect to sell at this price, based on the demand model and elasticity estimate
- Section Revenue — price multiplied by projected seats sold, with a delta showing gain or loss versus current pricing
- STH Resale Margin — the dollar profit (and percentage) a season ticket holder would make reselling at secondary market rates. Green = healthy (10%+), yellow = tight (0-10%), red = underwater
- Sell-through — the percentage of section capacity you expect to fill at this price

3. The revenue curve chart at the bottom plots every possible price against the revenue it would generate. Three reference lines help you decide: the red dashed line is your proposed price, the gray dotted line is the current face price, and the blue dashed line is the STH safe ceiling — the maximum price that keeps season ticket holders profitable on resale.

What to look for

The peak of the revenue curve is the theoretical revenue-maximizing price. But the STH safe ceiling constrains you — pricing above it means season ticket holders lose money on resale, which damages renewal rates. The sweet spot is between the current face price and the STH ceiling. If the current face price is already near the peak, there is little opportunity to capture. If the peak is well above the current face price and below the STH ceiling, you have a clear pricing opportunity.

EXAMPLE: Select "Mar 1 vs St. Louis City SC" (season opener) and section "LB_111_115" (lower bowl midfield). Face price is $128. Drag the slider to $150. Revenue increases from $218K to $241K (+$23K), sell-through drops only slightly from 100% to 94%, and STH margin stays at 18% (healthy green). This game has room to raise prices without hurting attendance or STH value. Now try a cold game like "Aug 26 vs Inter Miami" and notice the opposite: raising price drops sell-through sharply because demand is more elastic for midweek matches.

ACTION: Use this view in your weekly pricing review. For each upcoming game, test Balanced and Aggressive prices and confirm the STH margin stays green before approving a change.

STH Value Dashboard — Season Ticket Holder Resale Tracker

This view answers the most important question for your renewal campaign: can you prove that season tickets are worth the upfront commitment? It tracks resale value across every game and section tier, giving you the data to back up your pitch.

What you see

At the top, three KPI cards summarize the season-level picture: total season resale value (the aggregate dollar profit a STH can expect across all 17 games), average resale margin percentage, and the percentage of sections where the margin is healthy (10%+). A section tier filter lets you drill into specific fan segments — lower bowl midfield STH, upper bowl STH, club level STH, etc.

The bar chart breaks down resale margin by opponent. Each bar represents one home game. Tall green bars are high-value games where STH can resell at a significant profit — these are your Baja Cup matches, rivalry games, and marquee opponents. Short or red bars are low-demand games where STH would break even or lose money. A horizontal red dashed line marks break-even ($0).

The STH Value Statement

At the bottom of the view, a pre-written blockquote summarizes the resale value story in copy-paste-ready language for your renewal emails and marketing materials. It adapts to the selected tier filter. For example: 'Season ticket holders in the lower bowl can expect to resell for an average profit of $142 across the 17-game home season — an average margin of 11% per game.' This statement is generated from actual secondary market data, not a marketing claim.

Why this matters for the business

STH renewal is the single largest revenue driver for any MLS club. If you can prove that a $1,275 season package has a secondary market value of $1,417, the renewal pitch writes itself. The dashboard also shows which games drag down the value — these are the games where promotional activation (giveaways, theme nights, bundled experiences) has the highest ROI because it lifts the worst-performing bar in the chart.

EXAMPLE: Filter to 'upper_bowl'. The total season resale value shows $48/seat — positive but modest. Three games (midweek opponents) show negative margins. These are the games where the club should invest in promotional spend to boost demand, because every dollar of demand lift directly improves the STH renewal pitch for upper bowl holders.

ACTION: Before renewal season, export this data by tier. Use the STH Value Statement in your renewal emails. Customize messaging per section: premium sections get the resale profit story, upper bowl gets the promotional calendar story.

Performance Report — Backtesting & Model Accuracy

This is your accountability view — the one you show leadership to prove the pricing strategy is working. It combines backward-looking analysis (what happened in 2025) with forward-looking confidence metrics (how accurate the model is, and how robust it is to error).

2025 Backtest KPIs

Three headline metrics at the top: the 2025 average demand index (what percentage of capacity was filled on average), the model MAPE (Mean Absolute Percentage Error — how close predictions were to actual attendance), and the estimated revenue uplift the Balanced scenario would have generated versus the flat pricing that was actually used. For MAPE, anything under 15% is strong for live sports. The 8-14% range means predictions are off by 2,800-4,900 seats in a 35,000-seat stadium — directionally correct for pricing decisions.

2025 Revenue Retrospective

A bar chart shows how much revenue was left on the table for each 2025 home game, calculated by comparing what the club charged (face price) against what fans were actually paying on the secondary market. The biggest bars are your highest-value games — Club Tijuana (Baja Cup), LAFC (rivalry), Inter Miami (marquee). These are the games where data-driven pricing would have captured the most upside. Small bars (midweek, low-demand opponents) confirm those games were correctly priced or genuinely low-demand — the model would have recommended Conservative pricing on those anyway.

Sensitivity Analysis

A table shows what happens to revenue if the demand model is 20% wrong in either direction. The key insight: the Balanced scenario generates positive revenue uplift (+3% to +7%) even with significant model error, because the guardrails and alpha blending provide a safety net. The Aggressive scenario is riskier (can go negative with -20% error), which is why it should only be used on games with overwhelming secondary market confirmation.

Market Health Distribution

A pie chart shows the breakdown of section-game combinations by market health status: hot (secondary premium >35%), warm (20-35%), healthy (10-20%), and cold (<10%). A healthy distribution for a new club should show mostly warm and healthy segments, with hot spikes on rivalry and marquee games. If the cold segment is growing over time, it signals a broader demand issue that pricing alone cannot solve — you would need marketing and promotional intervention.

EXAMPLE: The 2025 retrospective shows ~$207K total revenue left on the table. The Club Tijuana match accounts for ~$38K of that — a single game where secondary premiums hit 50%+. LAFC is second at ~$29K. These two games alone represent 32% of the total opportunity, confirming that aggressive pricing on Baja Cup and rivalry matches has strong historical evidence.

ACTION: Present this view to the COO quarterly. Lead with the dollar amount left on the table, then show the sensitivity table to prove robustness. The message: even if we are wrong, we still make more money than flat pricing.
